JNI

1 Android User Interface

- 2 Multi-Language Support
- 3 Summary

From activity to widgets

University of Freiburg

Activity Application component that provides a screen [1].

User interface of an activity is build using View and ViewGroup objects [5].

View Basis unit for user interface, base for subclasses called *widgets*.

ViewGroup Base for subclasses called *layouts*.

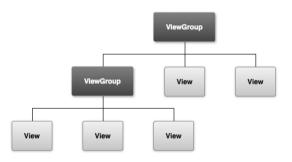

NI REIBURG

Android User Interface

View Hierarchy University of Freiburg

Android View Hierarchy containing ViewGroup objects as nodes and View objects as leafs.

Layout University of Freiburg

- Can be defined in an XML layout file [7].
- Similar to HTML layout development.
- Each element is a View or ViewGroup object or a subclass of these.
- ViewGroup objects contain more Views or ViewGroup objects.

Example XML layout

University of Freiburg

```
1 <?xml version="1.0" encoding="utf-8"?>
2 <LinearLayout xmlns:android="http://schemas.</pre>
     android.com/apk/res/android"
      android:layout_width="fill_parent"
3
      android:layout_height="fill_parent"
      android:orientation="vertical" >
   <TextView android:id="@+id/text"
      android:layout_width="wrap_content"
7
      android:layout_height="wrap_content"
      android:text="Hello, | I am a TextView" />
   <Button android:id="@+id/button"
10
      android:layout_width="wrap_content"
11
      android:layout_height="wrap_content"
12
      android:text="Hello, || I | am | a | Button | />
13
14 </LinearLayout>
```

40 + 40 + 43 + 4

Widget
University of Freiburg

- Subclass of View.
- Serves as interaction interface with user.
- Many fully implemented widges available.
 - Examples: Button, Checkbox, EditText and many more.
 - Advanced Example WebView: Displays web pages and can use JavaScript [6].
- Own implementation enables full customization of behavior.

Input Events
University of Freiburg

- Many ways to intercept events from user interaction.
- Approach for user interface events: Capture events from View objects the user interacts with [2].
- Two ways of implementation:
 - Overwrite existing callback method.
 - Define own event listener.
- Mostly used: Defining event listeners.

 ${\sf Example: Overwriting \ Callback \ Method}$

```
University of Freiburg
```

Example: Defining own Event Listener

University of Freiburg

```
public class MyActivity extends Activity {
   private OnClickListener myListener = new
       OnClickListener() {
     public void onClick(View v) {
3
        // Do something.
   };
7
   public void onCreate(Bundle state) {
     Button button = (Button)findViewById(R.id.
10
         myButton);
     button.setOnClickListener(myListener);
11
12
13
14 }
```

Android User Interface Intents and Broadcast Receivers

University of Freiburg

Intent Message to communicate between components. [3].

Can connect components in the same or in different applications.

Starts activities, background processes or notifies broadcast receivers.

Broadcast Receiver Can be registered to receive certain intents.

Example: Intent sent from system indicates incoming call and application stops playing music.

Example: Intent to call telephone number

University of Freiburg

- Intent starts activity by specifying what action should be performed.
- Note: Activity only implicitly given though action.

```
1 Intent intent = new Intent(Intent.ACTION_DIAL,
    Uri.parse("tel:5905-5635");
2 startActivity(intent);
```

Example: Broadcast receiver to react to phone calls University of Freiburg

Step 1: Create broadcast receiver as a new class.

```
public class MyPhoneReceiver extends
    BroadcastReceiver {
   @Override
   public void onReceive(Context context, Intent
       intent) {
     // Do something.
6 }
```

Example: Broadcast receiver to react to phone calls University of Freiburg

■ Step 2: Extend AndroidManifest.xml to register broadcast receiver to intents.

```
1<application ... >
   <receiver android:name="MyPhoneReceiver" >
     <intent-filter>
       <action android:name="android.intent.</pre>
           action.PHONE STATE" >
       </action>
     </intent-filter>
   </receiver>
8 </application>
```

Multi-Language Support

Overview University of Freiburg

- Done though localization: Switch language according to locale settings of the device [4].
- Helps reaching more users.
- Easy though separation of string resources and application code.
- Refer to string names in code and define strings in resource files.

- Default resources in res/values/strings.xml provides all strings used.
- Special language resource files like e.g. res/values-de/strings.xml provides adjusted strings.
- If no special resource file exists, default is used.

Multi-Language Support Example University of Freiburg

In Activity

```
1 tv = new TextView(this);
2 tv.setText(R.string.example);
```

In res/values/strings.xml

```
1 < string name = "example" > Example </ string >
```

■ In res/values-de/strings.xml

```
1 < string name = "example" > Beispiel < / string >
```

- User interfaces of activities are build through View and ViewGroup objects.
- ViewGroup subclasses are *layouts* that group other ViewGroup or View objects.
- View subclasses are *widgets* for user interaction like button, checkbox and so on.
- Enabling user interaction is implemented by capturing input events.
- Intents are messages and can be received through broadcast receivers.
- Multi-language support is implemented through resource files for strings.
